# Coping with depression and anxiety in Egyptian physicians during COVID-19 pandemic 

Ola Osama Khalaf, Mohamed A. Khalil and Reham Abdelmaksoud* ©

#### Abstract

Background: The COVID-19 pandemic is a public health emergency with a negative impact on mental health. Healthcare workers are one of the most vulnerable groups to psychological stress in pandemics especially COVID19. In this cross-sectional study, we assessed depression, stress, and coping among a sample of Egyptian physicians using an electronic survey. It included demographic data; Depression, Anxiety and Stress Scale-21 Items (DASS-21); and Brief Resilient Coping Scale (BRCS). Results: We found that the majority of the sample were females (61.2\%), in medical specialties (51.2\%), and living with vulnerable family members (92.4 \%). The majority (63\%) suffered from severe or extremely severe depression, $77.6 \%$ had extremely severe anxiety, and $72 \%$ suffered from stress. BRCS showed that only $17.1 \%$ had high resilient coping. Female physicians had significantly higher depression, anxiety, and stress scores of DASS than male physicians ( $p=0.001,<0.001$, and $<0.001$, respectively). The anxiety scale was significantly higher in those with chronic diseases ( $p=0.040$ ) while the stress scale was lower significantly in those with higher academic degree ( $p$ $=0.034$ ). Age had a significantly negative correlation with DASS anxiety ( $p=0.031$ ) and stress scores ( $p=0.037$ ). The BRCS score had a significantly negative correlation with the depression, anxiety, and stress scales of DASS ( $p=$ $0.018,0.014$, and 0.007 respectively). Conclusion: The COVID-19 pandemic has a negative impact on the psychological well-being of the studied Egyptian physicians. Prophylactic measures should be implemented to avoid development of psychiatric symptoms in physicians.

Keywords: COVID-19, Healthcare, Physicians, Depression, Anxiety, Stress, Coping, Egypt

## Background

In January 2020, the WHO classified the coronavirus disease 2019 (COVID-19) pandemic as a public health emergency [13].
Emergencies in public health including pandemics are known to have a negative impact on mental health at different levels [15]. At the individual level, it causes fear, helplessness, and stigma. As for communities, psychiatric morbidity may increase similar to what happened in SARS outbreak in 2003 [16].

[^0]Such emergencies threaten health and safety creating a state of insecurity and unpredictability. In the SARS outbreak, healthcare workers suffered from fears of being infected, infecting family/friends, stigma, and high levels of stress, anxiety, and depressive symptoms [11]. This is evident in the COVID-19 pandemic due to many factors: limited knowledge and resources, unavailable treatment, conflicting media messages, and social distancing. Healthcare workers are one of the most vulnerable groups to psychological stress in pandemics. Moreover, with COVID-19, healthcare workers suffer from longer working hours and scarce personal protective equipment (PPE) [15]. In addition, they are challenged with

[^1]deficient resource allocation to equally critical patients and rather impossible balance between their own needs being understaffed with the expanding number of patients. These pressures are intensified by time urgency and public and media scrutiny $[6,19]$.
Many studies assessed factors mediating psychiatric morbidity during pandemics. This includes profession (doctor/nurse), marital status, presence of social support, training competency, and coping mechanisms [7].
Coping is an important mediator between stress and mental illness such as anxiety and depression [4].
The literature on COVID-19's effect on mental health is currently expanding but is still limited. In this study, we aim at assessing the depression, anxiety, and stress among a sample of physicians in different specialties in Egypt and also determining their ability to cope with these stresses. We assume that COVID-19 has a negative impact on the psychological health of physicians. Additionally, we assume that proper coping skills neutralize the effect of COVID-19.

## Methods

This was a cross-sectional study using a convenient sample. An anonymous survey was distributed among doctors through social media via link. The link was sent to doctors' groups of specific specialty or sent individually. The survey was time-limited to 3 months and was carried out from March to May 2020 during the COVID-19 pandemic.
The survey was written in English and was titled Survey among Medical staff. It started with a must-answer question about whether or not the candidate would like to participate or not.
The questionnaire included demographic data; the Depression, Anxiety and Stress Scale-21 Items (DASS-21) [12]; and Brief Resilient Coping Scale (BRCS) [17].
We included physicians from both genders and different ages and years of experience. Physicians included were working in governmental general hospitals. They treated patients with COVID-19 from different medical complications or comorbidities according to their specialty. History of psychiatric disorders or treatment with psychotropics was excluded by history taking.
Clinical specialties were clustered into 3 categories: surgical, medical, and supportive. Supportive group of specialty includes microbiology, nuclear medicine, pathology, radiology, anesthesiology, clinical genetics, and radiotherapy according to the Dutch classification [3].
Demographic data included age, gender, marital status, academic level, occupation, specialty, and working years.
Some questions were added to assess the risk to COVID-19 to self (like suffering from chronic illness) and to others (living with vulnerable groups). A question
to assess workload (working hours/week during last month) was added.
The DASS-21 consists of 3 self-report scales that assess depression, anxiety, and stress during the past 7 days. The depression scale assesses dysphoria, hopelessness, devaluation of life, self-deprecation, lack of interest, anhedonia, and inertia. The anxiety scale assesses autonomic arousal, skeletal muscle effects, situational anxiety, and subjective experience of anxious affect. The stress scale assesses difficulty relaxing, nervous arousal, and being easily upset/agitated, irritable/overreactive, and impatient. Responder has to choose between 4 answers ranging from "did not apply at all" to "apply very much." Higher scores indicate severity. Scores for the three scales are calculated by summing the scores for the relevant items, and the severity of each scale is defined (normal, mild, moderate, severe, or extremely severe) (Table 1) [12].

Coping was assessed using the Brief Resilient Coping Scale. It is a standardized 4-item scale that evaluates the resilience and coping to stressors. Responders have 5 choices in each question: does not describe me at all, does not describe me, neutral, describe me, or describe me very well. Higher scores indicate higher resilience. The total score classifies responders to low, medium, and high resilience copers (Table 2) [10].

Data were analyzed using the Statistical Package for the Social Sciences (SPSS) version 20 [9]. Mean and standard deviation were used for describing the numerical data while count and frequency described the categorical data. Comparisons between 2 groups were done by Student's $t$ test and chi-square test. One-way ANOVA was used for comparing 3 groups. Association between numerical groups was done by Pearson's correlation test.
There was no missing data.

## Results

One hundred and seventy physicians participated in the survey over the 3 -month period. Two thirds of them were females ( $61.2 \%$ ) with mean age of 36.5 years. Other demographic data are shown in Table 3.

Physicians in medical specialties were $51.2 \%$ of total participants; meanwhile, surgeons were $25.88 \%$ and supportive specialty physicians were $22.94 \%$. Physicians

Table 1 DASS interpretation and categories

| DASS interpretation | Depression | Anxiety | Stress |
| :--- | :--- | :--- | :--- |
| Normal | $0-9$ | $0-7$ | $0-14$ |
| Mild | $10-13$ | $8-9$ | $15-18$ |
| Moderate | $14-20$ | $10-14$ | $19-25$ |
| Severe | $21-27$ | $15-19$ | $26-33$ |
| Extremely severe | $28+$ | $20+$ | $34+$ |

Table 2 BRCS interpretation and categories

| BRCS interpretation | Score range |
| :--- | :--- |
| Low resilient copers | $4-13$ points |
| Medium resilient copers | $14-16$ points |
| High resilient copers | $17-20$ points |

worked 27.36 h per week in average. The majority of them (92.4\%) were living with vulnerable family members (Table 3).
The depression scale of DASS was $12.54 \pm 6.72$ in which $63 \%$ of physicians had either severe or extremely severe depression and only $7 \%$ of them were normal on this scale. Meanwhile, the anxiety scale was $14.44 \pm 7.37$ and $77.6 \%$ of physician had extremely severe anxiety. Twenty eight percent of physicians were normal on stress score (Table 3).
The Brief Resilient Coping Scale score was $13.45 \pm$ 2.95. Half of physicians were low resilient copers, one third of them were medium resilient copers, and $17.1 \%$ were high resilient copers (Table 3).
Female physicians were significantly higher in the depression, anxiety, and stress scales of DASS than male physicians ( $p=0.001,<0.001$, and $<0.001$, respectively). The anxiety scale was significantly higher in those with chronic diseases ( $p=0.040$ ) while the stress scale was lower significantly in those with higher academic degree ( $p=0.034$ ). Marital status, specialty, years of experience, and living with a vulnerable family member did not show significant differences in DASS scores (Table 4).
The Brief Resilient Coping Scale score did not show significant differences in different categories of gender, marital status, academic degree, specialty, years of experience, living with vulnerable family members, and chronic diseases (Table 4).
Age had a significantly negative correlation with DASS anxiety ( $p=0.031$ ) and stress scores ( $p=0.037$ ). Weekly working hours were not significantly correlated with any of DASS scores (Table 5).
The Brief Resilient Coping Scale score had a significantly negative correlation with the depression, anxiety, and stress scales of DASS $(p=0.018,0.014$, and 0.007 , respectively) (Table 5).

## Discussion

Our study describes the psychological impact and mental health of the medical staff in a convenient sample of Egyptian physicians.
The majority of physicians had either severe or extremely severe depression while $77.6 \%$ of them had extremely severe anxiety. Anxiety was significantly higher in those with chronic diseases; this has been proven by several researches that depression and anxiety occur with chronic diseases [2] but also the underlying chronic
disease such as hypertension, respiratory system disease, and cardiovascular disease may be risk factors in severe COVID-19 patients compared with non-severe ones [20]; this may rise the anxiety among medical staff members who suffer from chronic illness.
Unexpectedly, the weekly working hours were not significantly correlated with DASS. This can be explained by the precautionary measures against COVID-19 which included decreasing the workforces in some specialties (apart from frontline healthcare physicians) resulting in a wide range of working hours for our sample. In addition, the unusual situation related to COVID-19 outbreak may be the main reason for higher score scores of DASS regardless of the workload.

Stress was found to be less among higher education level. This might be explained and understood that senior physicians are less exposed as they have fewer working hours than junior one and more experienced in dealing with critical situations. Moreover, seniors are elder and age was found to be inversely correlated to anxiety and stress scales of DASS. As age advances, the personality becomes stable and less confused under stress as persons become comparatively free of neurotic anxiety [14].

Further analysis for the results showed significant difference between males and females as regards levels of depression, anxiety, and stress as measured by DASS-21 and also as regards resilience as measured by BRCS. This higher symptom prevalence in females resonates well with results from surveys conducted in other countries $[18,20]$ and is also similar to a Chinese study conducted on 246 medical staff during the COVID-19 pandemic, the incidence of anxiety in female medical staff was higher than that in male, and the score of self-rating anxiety scale in female medical staff was higher than that in male [8]. Women usually show more reactivity than men in neural networks associated with fear and arousal responses [5].
As regards the significantly positive correlation between the triad of depression, anxiety, and stress, it could be explained that all of them have similar pathophysiology where there are abnormalities in the regulation of the hypothalamic-pituitary adrenal axis and the sympatho-adrenomedullary system [1].

The significant negative correlation between this triad and resilience coping was suggested by previous researchers who found that coping may play an important role in mediating the outcomes of stressful events, including anxiety, depression, and other psychological distress [4].

## Conclusion

Therefore, we can conclude that the psychological wellbeing of the studied Egyptian physicians in this sample

Table 3 Demographics and clinical characteristics of the physicians

| Physicians ( $N$ 170) |  | Number/frequency |
| :---: | :---: | :---: |
| Age in years (mean $\pm$ SD) |  | $36.47 \pm 5.08$ |
| Gender | Males | 66/38.8\% |
|  | Females | 104/61.2\% |
| Marital status | Single | 43/25.3\% |
|  | Married | 123/72.4\% |
|  | Divorced or widow | 4/2.4\% |
| Academic degree | Bachelor | 9/5.3\% |
|  | Master | 66/38.8\% |
|  | MD | 95/55.9\% |
| Job | Resident | 17/10.0\% |
|  | Assistant lecturer | 38/22.4\% |
|  | Lecturer | 57/33.5\% |
|  | Associate professor | 16/9.4\% |
|  | Professor | 10/5.9\% |
|  | Other | 32/18.8\% |
| Specialty | Surgical specialties | 44/25.88\% |
|  | Medical specialties | 87/51.17\% |
|  | Supportive specialties | 39/22.94\% |
| Years of experience | Less than 5 years | 14/8.2\% |
|  | 5-10 years | 49/28.8\% |
|  | More than 10 years | 107/62.9\% |
| Working hours per week (mean $\pm$ SD) |  | $27.36 \pm 25.67$ |
| Living with vulnerable family members | No | 13/7.6\% |
|  | Yes | 157/92.4\% |
| DASS ${ }^{\text {a }}$ depression score (mean $\pm$ SD) |  | $12.54 \pm 6.72$ |
| DASS depression | Normal | 12/7.1\% |
|  | Mild | 18/10.6\% |
|  | Moderate | 33/19.4\% |
|  | Severe | 44/25.9\% |
|  | Extremely severe | 63/37.1\% |
| DASS anxiety score (mean $\pm$ SD) |  | $14.44 \pm 7.37$ |
| DASS anxiety | Normal | 9/5.3\% |
|  | Mild | 7/4.1\% |
|  | Moderate | 10/5.9\% |
|  | Severe | 12/7.1\% |
|  | Extremely severe | 132/77.6\% |

| Physicians ( $\boldsymbol{N} \mathbf{1 7 0 )}$ |  | Number/frequency |
| :--- | :--- | :--- |
|  | Medium resilient copers | $56 / 32.9 \%$ |
|  | High resilient copers | $29 / 17.1 \%$ |

${ }^{a}$ DASS Depression, Anxiety and Stress Scales
${ }^{\mathrm{b}}$ BRCS Brief Resilient Coping Scale
is affected negatively by the COVID-19 pandemic suffering from depressive, anxiety, and stress symptoms. These results should raise our attention to the medical staff and their mental health status, so we recommend more prevention efforts such as screening for mental health
problems, psycho-education for stress management strategies and acquiring healthy coping skills (setting a daily routine, avoiding too much news about COVID19), and psychosocial support.

${ }^{\text {a }}$ DASS Depression, Anxiety and Stress Scales
${ }^{\mathrm{b}}$ BRCS Brief Resilient Coping Scale

Limitations of this study include the relatively small sample size, and the whole data were self-rated which may limit the data generalizability. Also, the effect of direct contact with COVID-19 patients was not studied. We recommend in future studies increasing the staff sample size and categorizing the experiences based on profession.
